

Cognitive Models

CS 347

Michael Bernstein

Last time

Visualizations can be represented as **encodings** that map from **data to marks & visual attributes** based on **data types**

Our **cognitive and perceptual systems determine which encodings are effective**: we (mis)read data if encoded poorly

Active research at frontiers investigating **how users can create effective visualizations** and **how readers take information away from them**

Today

The model human processor

GOMS, KLM

Generative AI simulation models

Building a better mouse(trap)

[Card and Moran 1988]

Doug Engelbart and Bill English felt that their **mouse was an interim device**, and wanted to make something better

But none of their inventions were actually improving target acquisition speeds

So, Stu Card and Tom Moran tested the mouse in the lab on a variety of pointing tasks

Building a better mouse(trap)

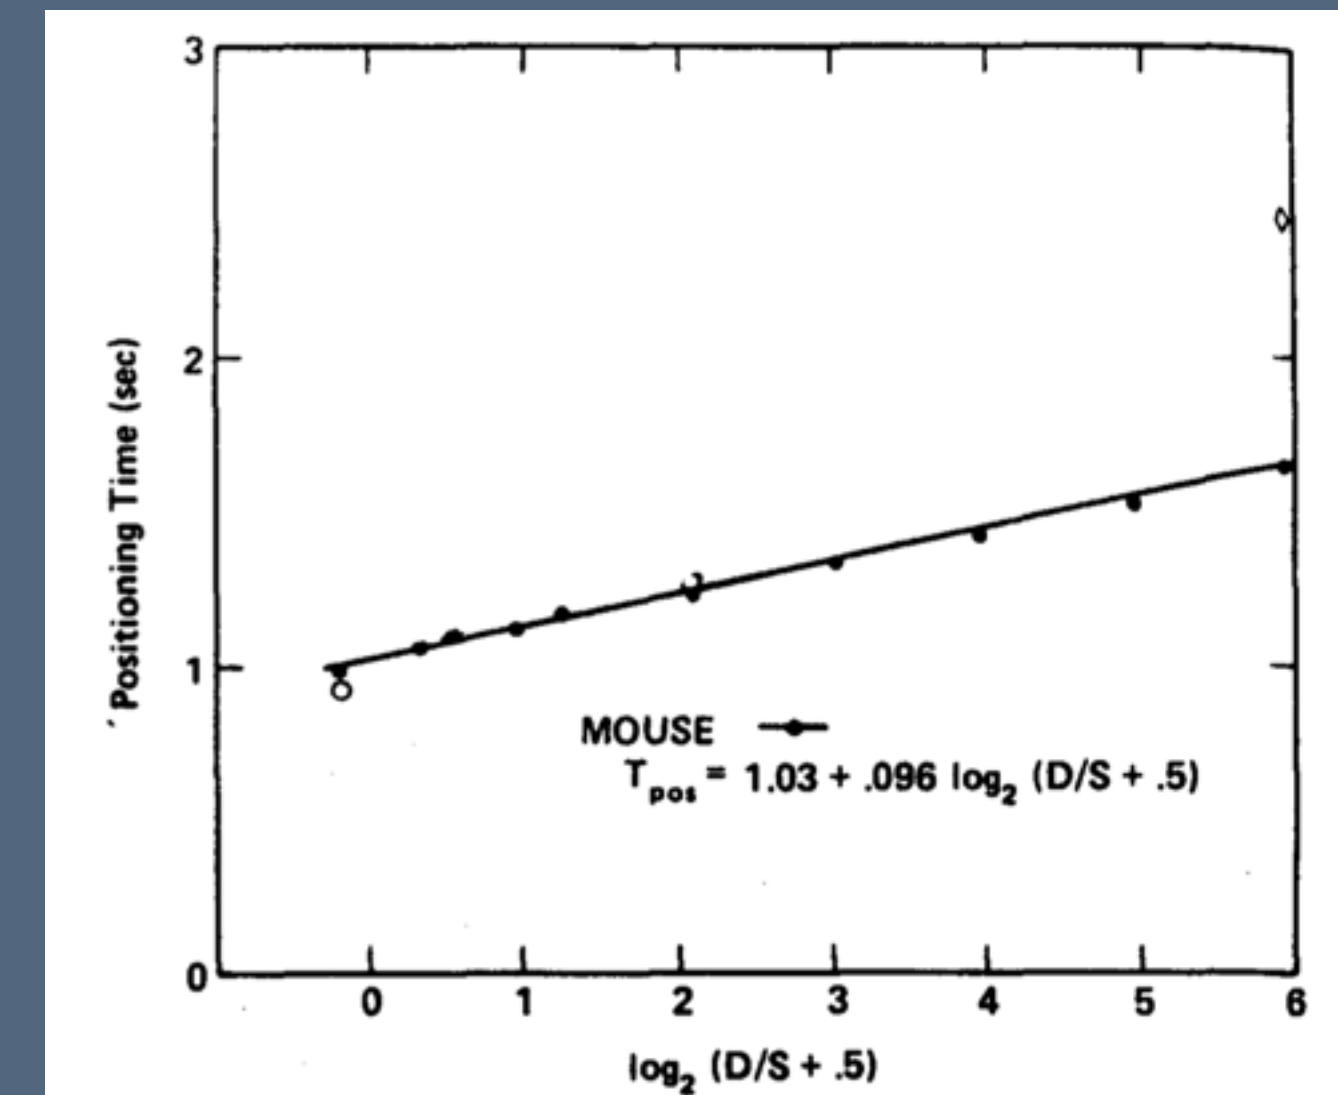

[Card and Moran 1988]

Performance was very well modeled by **Fitts's Law**.
(Fitts's Law is about human pointing, not mice.)

$$T = a + b \log(D/S + 0.5), D = \text{distance}, S = \text{target size}$$

Moreover, the mouse's constant of proportionality
($b = 0.96 \text{ sec/bit} = 10.4 \text{ bits/sec}$) is approximately the
same with the mouse as with the hand alone — **so the
mouse is near optimal, you actually can't do better!**

**Here, modeling solved a problem that engineering
couldn't.**

Line = Fitts's Law prediction
Dots = measured mouse time

“User technology includes hardware and software techniques [...] but it must include a **technical understanding of the user** and of the nature of human-computer interaction. This latter part, **the scientific base of user technology**, is necessary in order to understand **why** interaction techniques are (or are not) successful, to help us **invent** new techniques, and to pave the way for machines that aid humans in performing significant intellectual tasks.”

[Card and Moran 1988]

Model Human Processor

The Model Human Processor

[Card, Moran and Newell 1983]

**A unified, low-level engineering
model of user task completion**

Based on empirical research, contains
internal processors for cognition and
motor movement

Similarly, empirically-estimated
working and long term memory

Why Model Humans?

So we can **better understand why** what works works, and **why** what doesn't work is broken

Apply MHP to **predict time and accuracy** of using interface

Apply MHP as a **simulation of human user** (with constraints) to **evaluate** interface designs

What to pay attention to in this section

Track the **translation** from **empirical psychology** into **engineering decisions** in how the Model Human Processor works

The point is less to memorize specific results, but instead to understand how these results get translated, and why

The result is, effectively, a human “**algorithm**” that **mimics the basics of our perceptual, motor, and cognitive behaviors.**

Perception

Time needed to integrate/fuse perceptual experience of the world

$T_P = 100 \text{ msec}$ ("quantum of experience")
 = 10 fps: Rate needed for film to be perceived as continuous

Perception of Causality

[Michotte 1946]

What do you see?

Perception of Causality

[Michotte 1946]

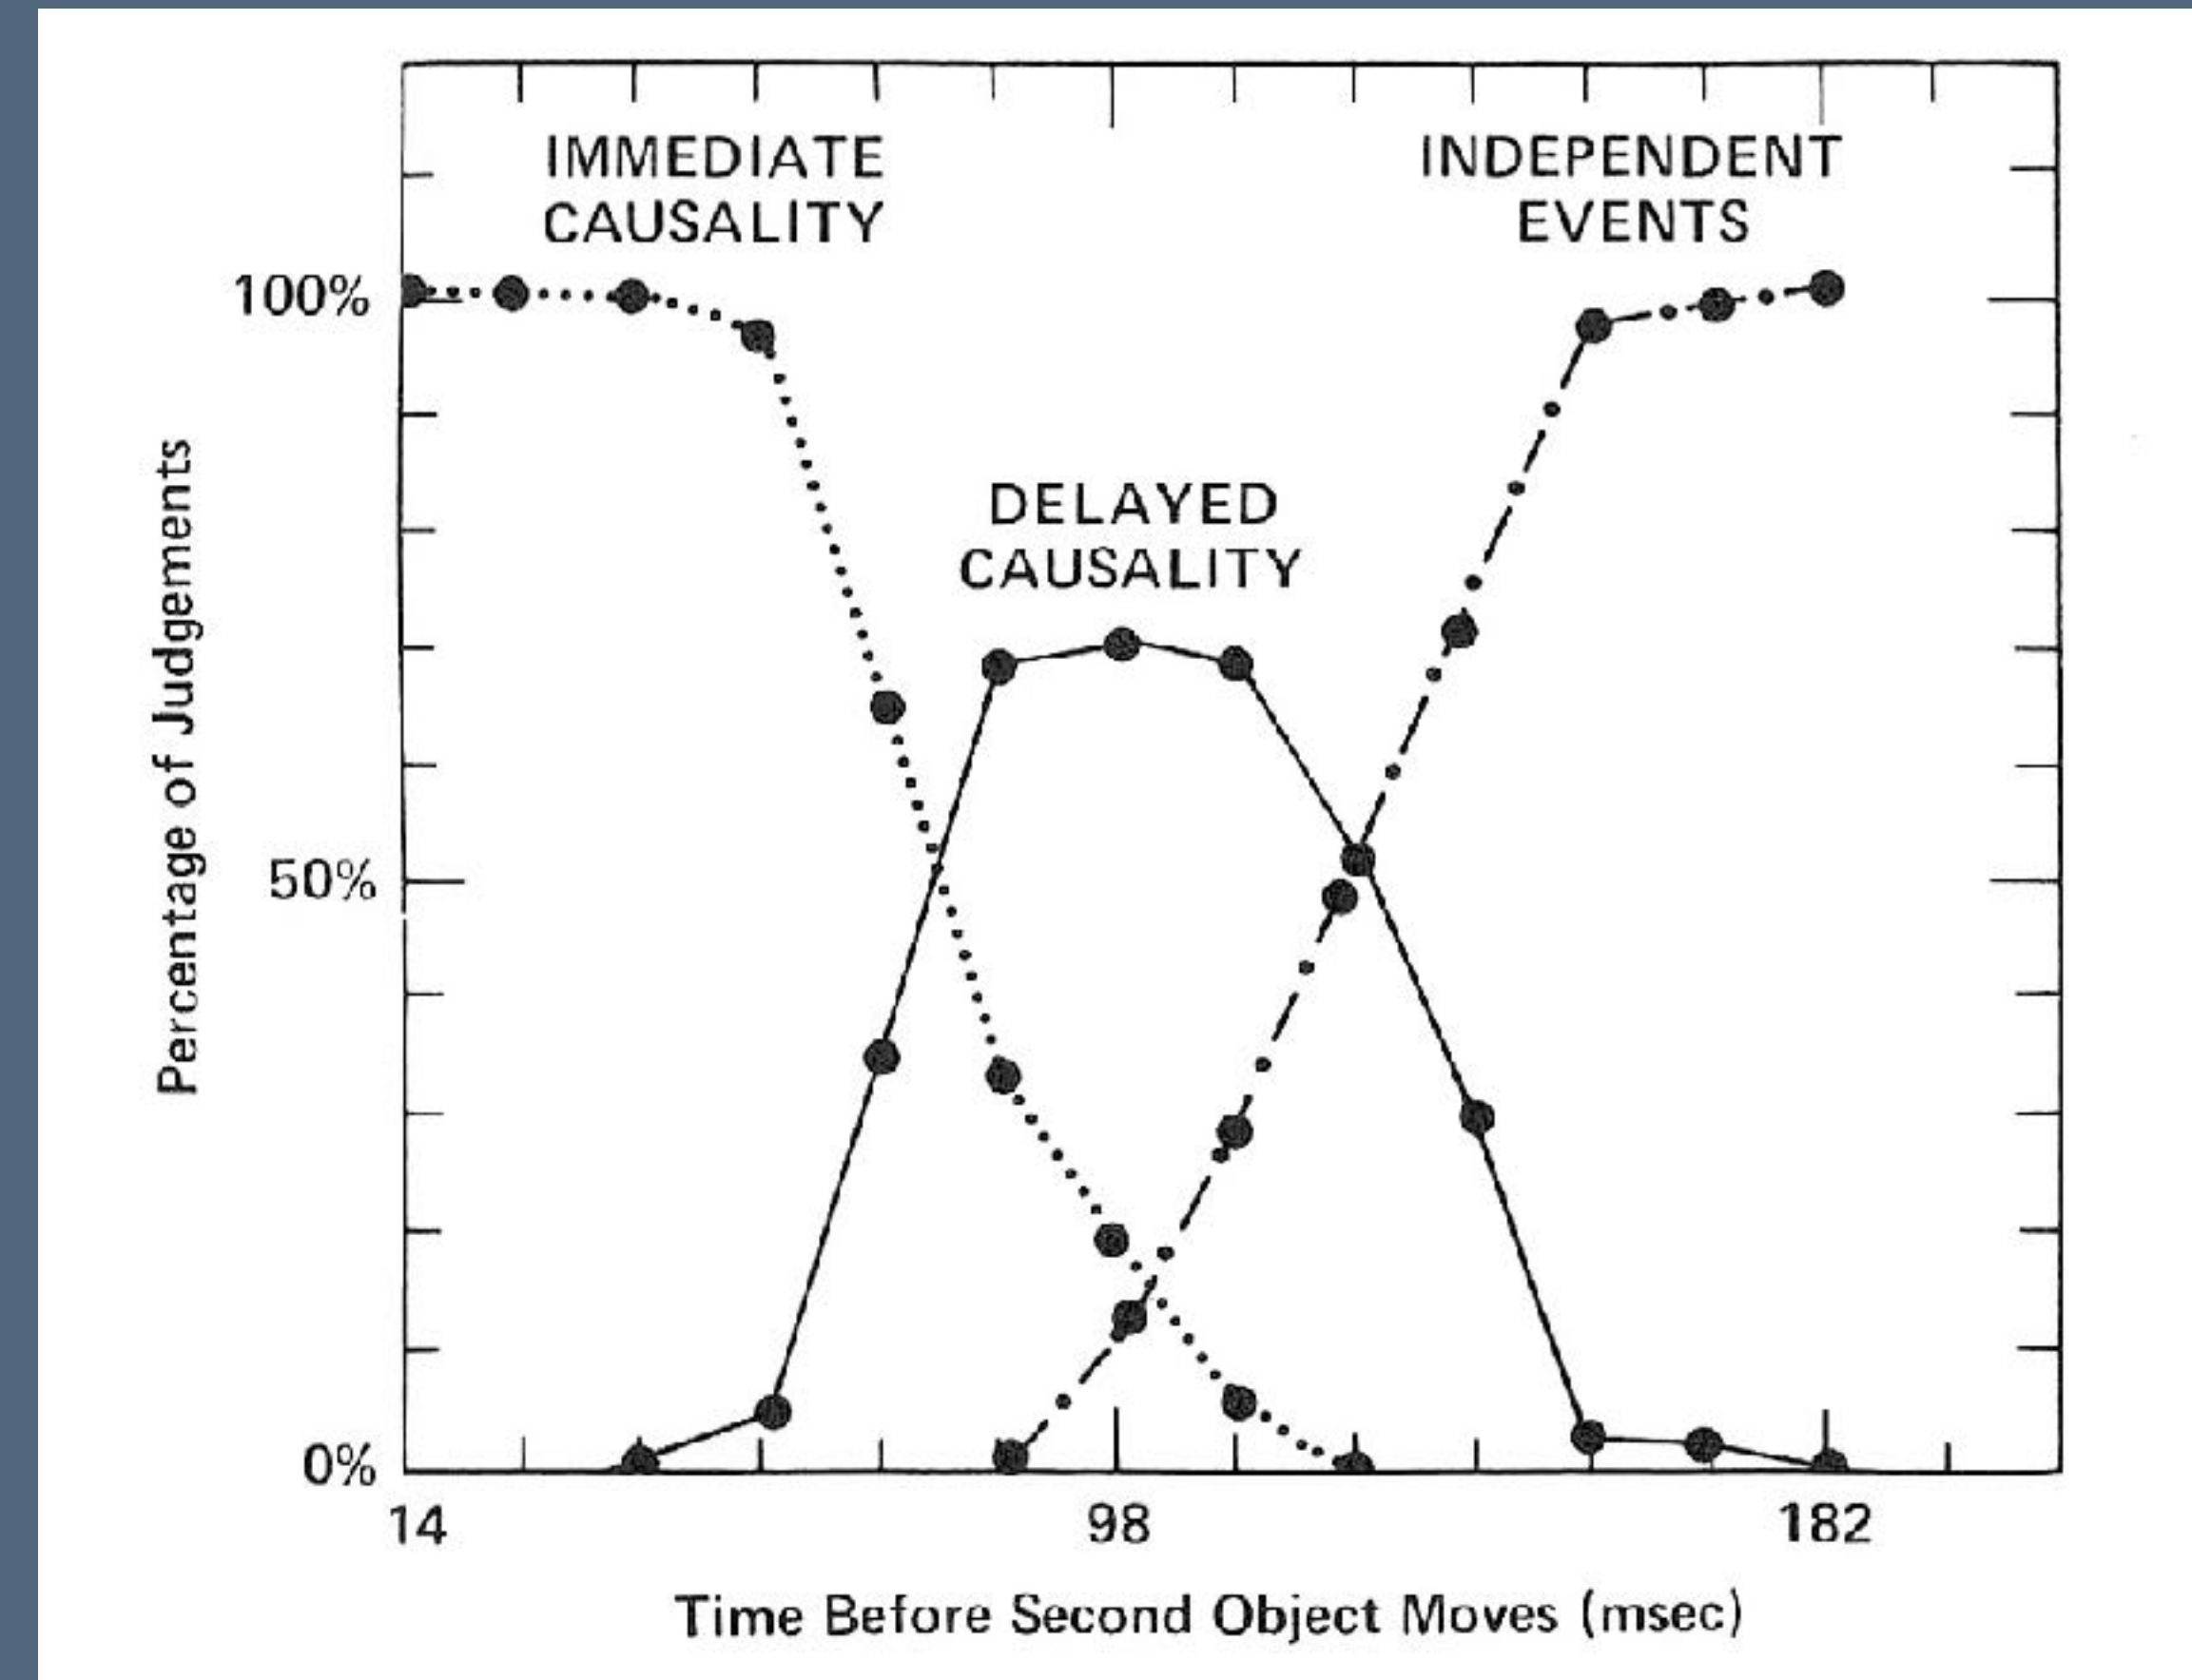

What do you see?

Perceptual Processor

Time needed to integrate/fuse
perceptual experience of the world

$T_P = 100$ msec (“quantum of experience”)
= 10 fps: Rate needed for film to be
perceived as continuous
= **rate needed to imply causality**

Memory

Perceptual processor puts information into (vis/aud/...) **sensory store**

very fast decay 200-1500 msec
small units of information (e.g. letters)

Some info then **chunked** and put into longer decay **working memory**

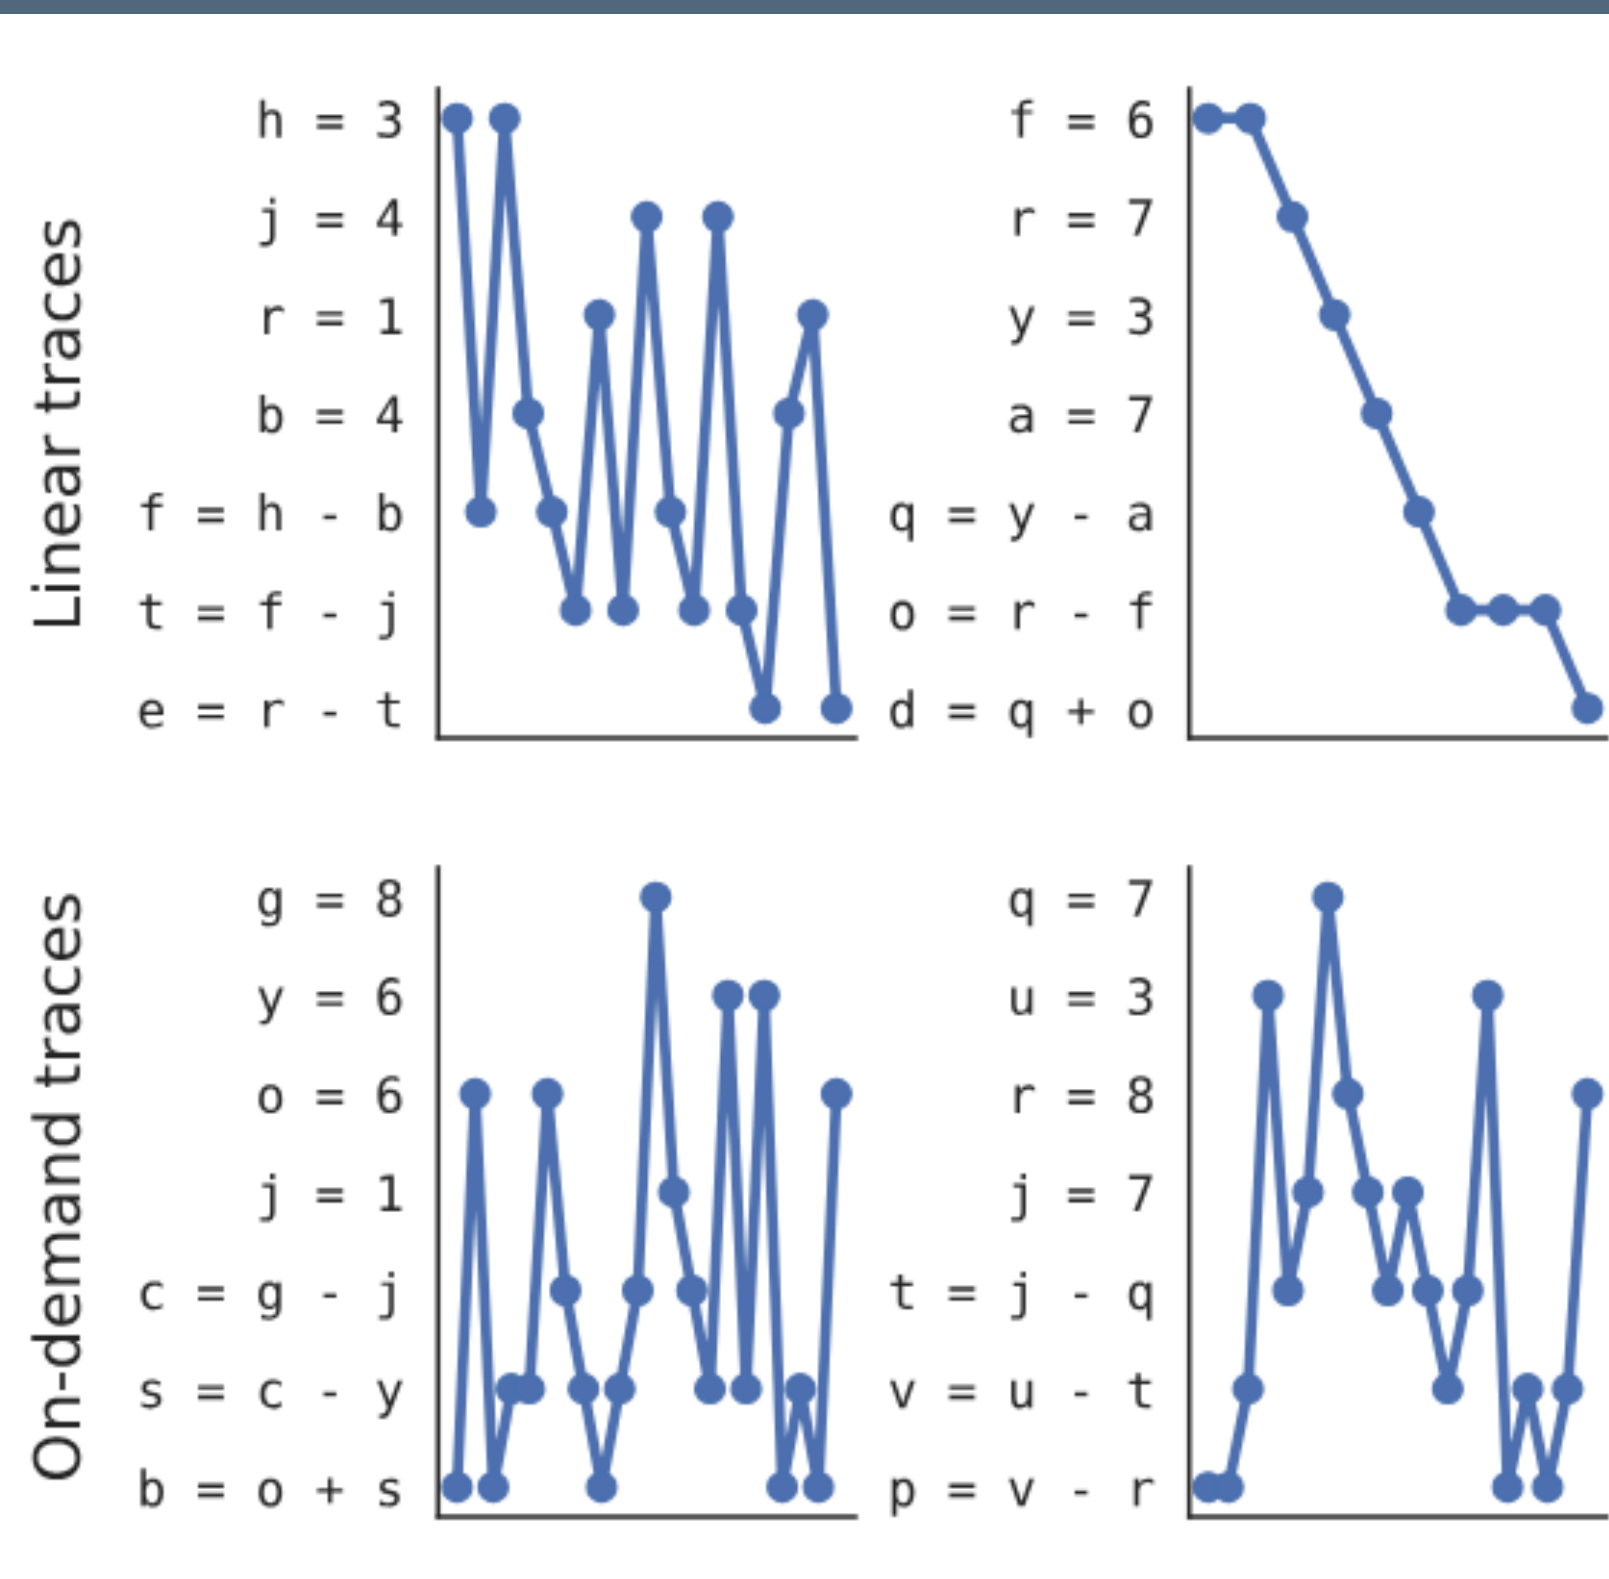

decay 5-225 sec (content dependent)
7 +/- 2 chunks (e.g. words)

Some info then recoded (semantically) and put into **non-decaying long-term memory**

WM and Program Tracing

[Crichton, Agrawala, Hanrahan 2021]

Examines how people trace simple programs

Order in which lines are exposed (linear vs. on-demand)

How often need to re-visit a line already seen

WM holds ~ 7 (variable, value) pairs

Both linear and on-demand orderings frequently used

People make different WM errors depending on ordering strategy with more errors using on-demand

Cognition

Time needed to observe WM and operate on it (e.g. check if 2 chunks match)

$$T_c = 70 \text{ msec}$$

Fundamentally serial

One locus of attention at a time

Motor Proc.

Time needed to take input command from cognitive processor and execute it with body

$$T_M = 70 \text{ msec}$$

Example: pianist (up to 16 finger movements/sec)

Motor Experiment

Ask person move pen back and forth as quickly as possible:

Open loop: $68 \text{ reversals} / 5 \text{ sec} = 74 \text{ msec/reversal}$

Closed loop: Participant perceives if stroke is staying within lines, sends info to the cognitive processor, which advises the motor processor to adjust.

Predicted time = $T_P + T_C + T_M = \sim 240 \text{ msec}$

Empirical time = $20 \text{ corrections} / 5 = 250 \text{ msec}$

Using the Model Human Processor

Low level task: I will flash 2 symbols **x** and **y** on screen serially,
press a key if they are both numbers

Clocks starts when 2nd symbol **y** is flashed

Move symbol **y** into visual store WM

T_p

Recognize both symbols **x** and **y** as codes

$+T_c$

Classify the both codes as numbers

$+T_c$

Match the fact that they are both numbers

$+T_c$

Initiate motor response

$+T_c$

Process motor command

$+T_m$

Approx 450 (180-980) msec

GOMS

Goals: what the user seeks to achieve

Operators: low-level operations

Methods: compositions of operations together

Selection rules: how to decide between multiple available methods

Given this specification, a system can trace a path that a user would take through a system to achieve their goal and report how long it would take

KLM [Card, Moran and Newell 1980] [Raskin 2000]

Keystroke Level Model: a specific model in the GOMS family. Designed to be quick and easy to use, no need to build a prototype.

Provides a bunch of operators and methods: not GOMS from scratch

Six operators: push a key, point to a target on the display, moving hands between keyboard/mouse/etc., drawing a line (seems extraneous to me), making a decision about the next step, waiting for system response

Operator	Time
K ey/Click	0.20
P oint	1.1
H oming	0.4
D raw	$.9n_D + .16 l_D$
M ental	1.35
Sys. R esp.	Depends

KLM [Raskin 2000]

Example [via Wael Aboelsaadat]: minimize a window by clicking on the button, or using the keyboard shortcut (hands initially on mouse)?

Clicking on the button:

Mentally prepare, Point, Click:

$$\text{MPK} = 1.35 + 1.1 + 0.2 = 2.65\text{sec}$$

Keyboard shortcut:

Home to keyboard, Mentally prepare, Key (type) cmd-M:

$$\text{HMKK} = 0.4 + 1.35 + 0.4 = 2.15\text{sec}$$

Operator	Time
K ey/Click	0.20
P oint	1.1
H oming	0.4
D raw	$.9n_D + .16 I_D$
M ental	1.35
Sys. R esp.	Depends

Raskin's KLM Rules

First break task into H,P, K,D, R (then use rules)

R0: Insert M

In front of all K

In front of all P's selecting a command (not setting args)

R1: Remove M btw fully anticipated operators

PMK to PK

R2,R3: if MKs form cog. unit delete all Ms except first

typing "4564.23": MKMKMKMKMKMKMK to MKKKKKKK

typing "enter" "enter": MKMK to MKK (redundant terminator)

R4: if K terminates freq. used fixed length string (e.g. cmd)

delete M in front of it

typing "cd" "enter": MKKMK to MKKK

typing "cd" "class" "enter": MKKKMKKKKKMK (do not remove last M)

Operator	Time
K ey/Click	0.20
P oint	1.1
H oming	0.4
D raw	$.9n_D + .16 I_D$
M ental	1.35
Sys. R esp.	Depends

Converting Temperature

Convert 92.5

Assume focus on dialog,
hands at keyboard, typing
enters text into text field

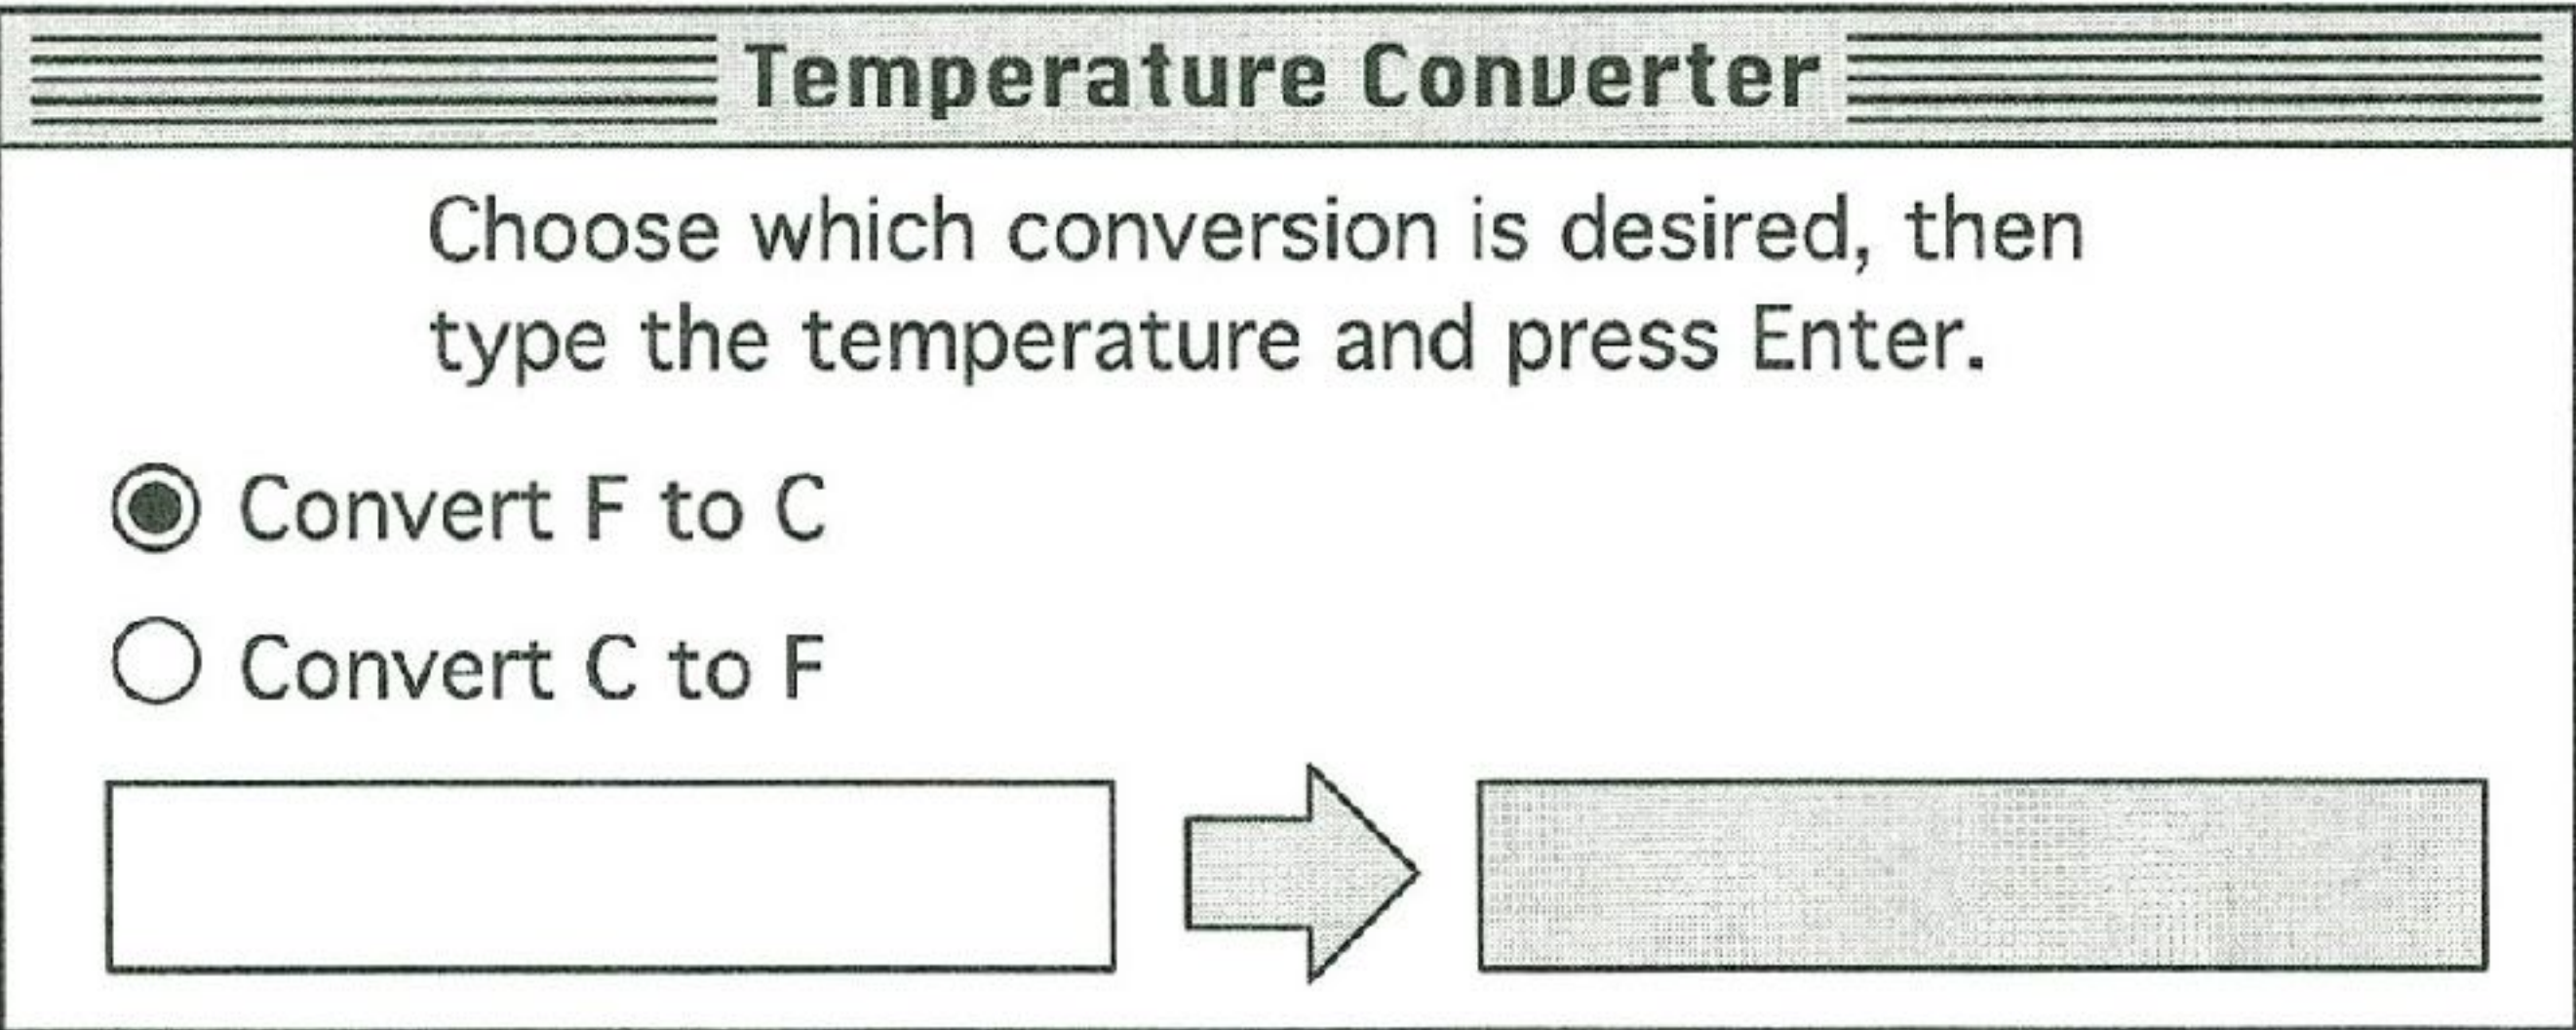

Assuming goal C to F

H PK H KKKK K to H MPMK H MKMKMKMK MK to H MPK H MKKKK MK (7.15sec)

Assuming goal F to C

KKKK K to MKMKMKMK MK to MKKKK MK (3.7sec)

Avg time: 5.4sec

Temperature Converter

Choose which conversion is desired, then
type the temperature and press Enter.

☒ Convert F to C
☐ Convert C to F

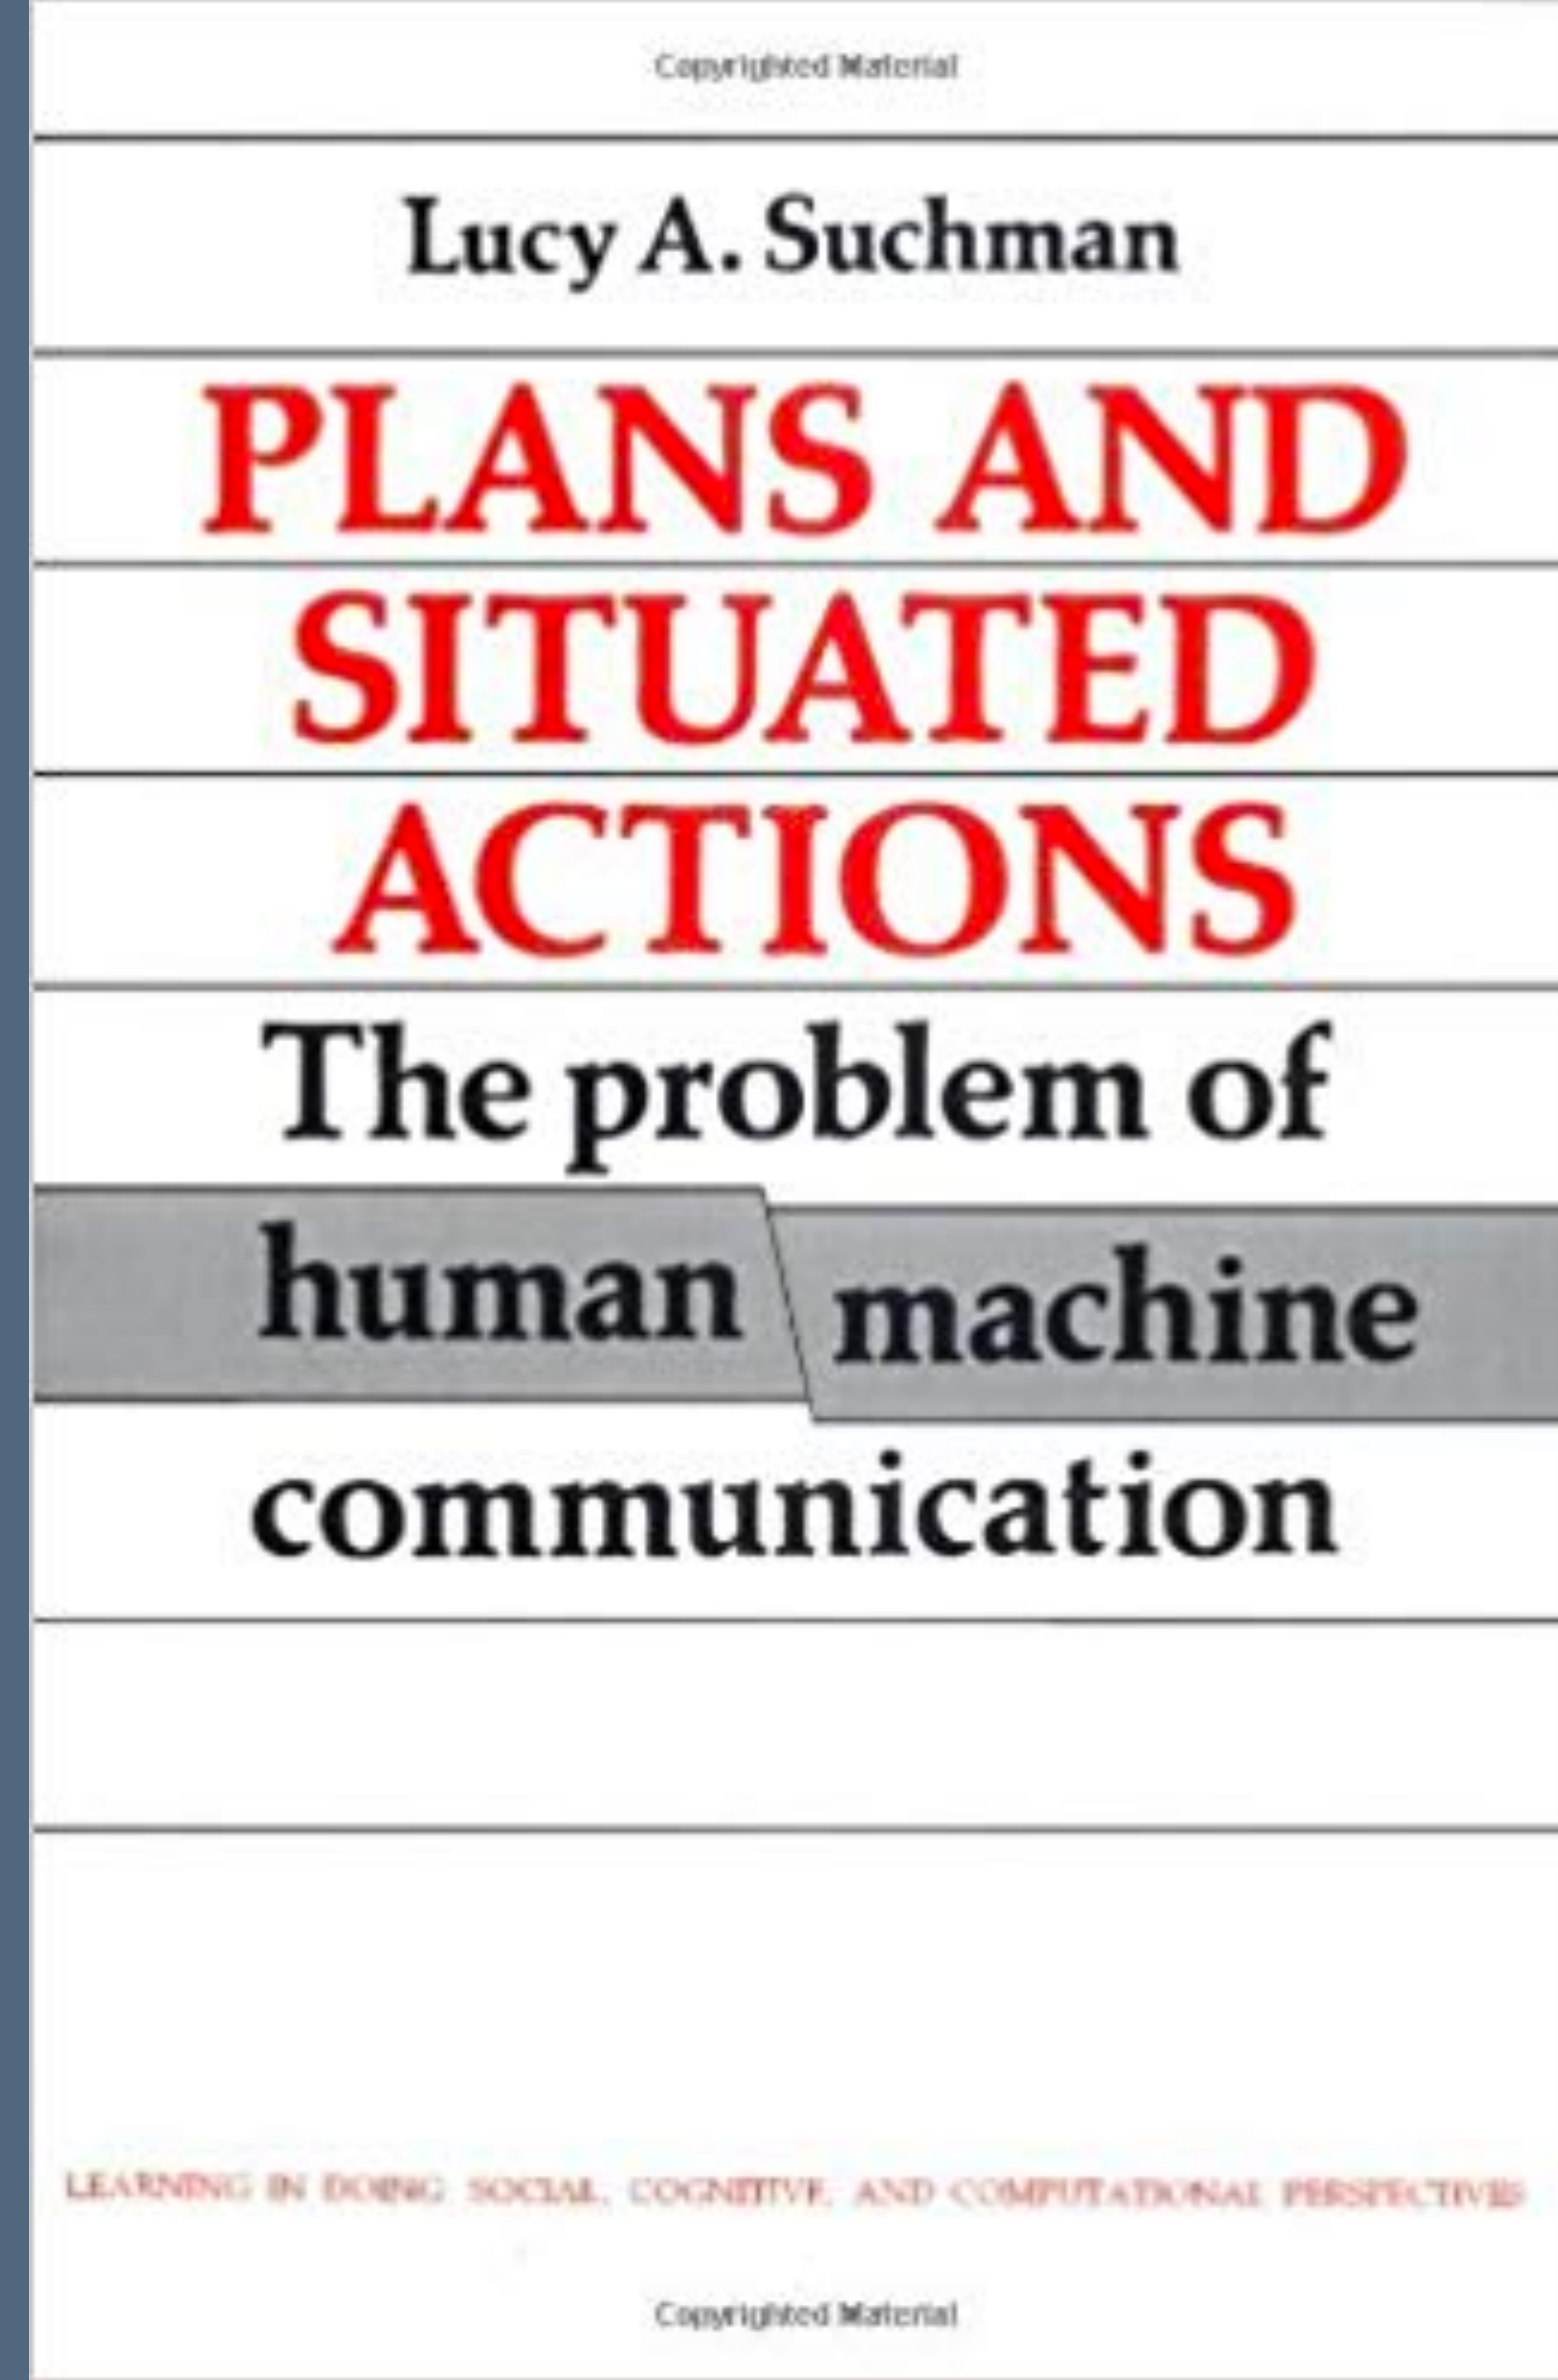

→

Where are they now?

Models as inhuman models of how we act

Plans cannot succeed in complex
environments, which instead require
constant reflection and reorientation
[Suchman 1988]

Anthropological comparison: how people
perform wayfinding

GOMS is Sensitive to Methods and Operators

In GOMS, the **developer defines operators** and **methods**. Need to be **careful** to make sure they are **appropriate to task** and **context**

“There’s no accounting for taste” — GOMS will not object to a baroque set of operations that a user might never use in practice

Outcomes will depend strongly on exactly which operators and methods you define and make available to the model

GOMS Is (Relatively) Quantitative

GOMS explicitly **capture low-level cognitive behaviors** of interest **quantitatively**

The Model Human Processor estimates were based on careful lab studies

But **absolute numbers are less reliable than relative values**

Can be less work than a user study

Today's state

Low-level cognitive models (e.g. GOMS and KLM) have fallen out of favor, largely because they require **substantial effort** to create, vs. directly prototyping

However, for low-level optimizations and interface decisions, cognitive models can be very useful

And, they remain important to HCI as an example of how **grounding our designs in psychological methods** and results can lead to more effective approaches and insights

Generative AI Simulation Models

A Complementary Strategy

There are two strategies to creating models [Bruch & Atwell 2015]:

Low-dimensional realism, with a **specific but interpretable** model like the Model Human Processor

High-dimensional realism, with a **broad but uninterpretable model**

Modern large language models have learned much about human cognition, attitudes, and behavior through their training data: can they power this latter class of cognitive model?

LLMs have trained on a range of human behaviors

Large language models can be prompted to take on a variety of backgrounds, experiences and traits [Park et al. 2022]

[name] is a
[description]

Generative agents

[Park et al. 2023]

Generative agents [Park et al. 2023]

Agents that draw on generative models to simulate believable human behavior

A student athlete agent in the morning wakes up and:

Brushes teeth

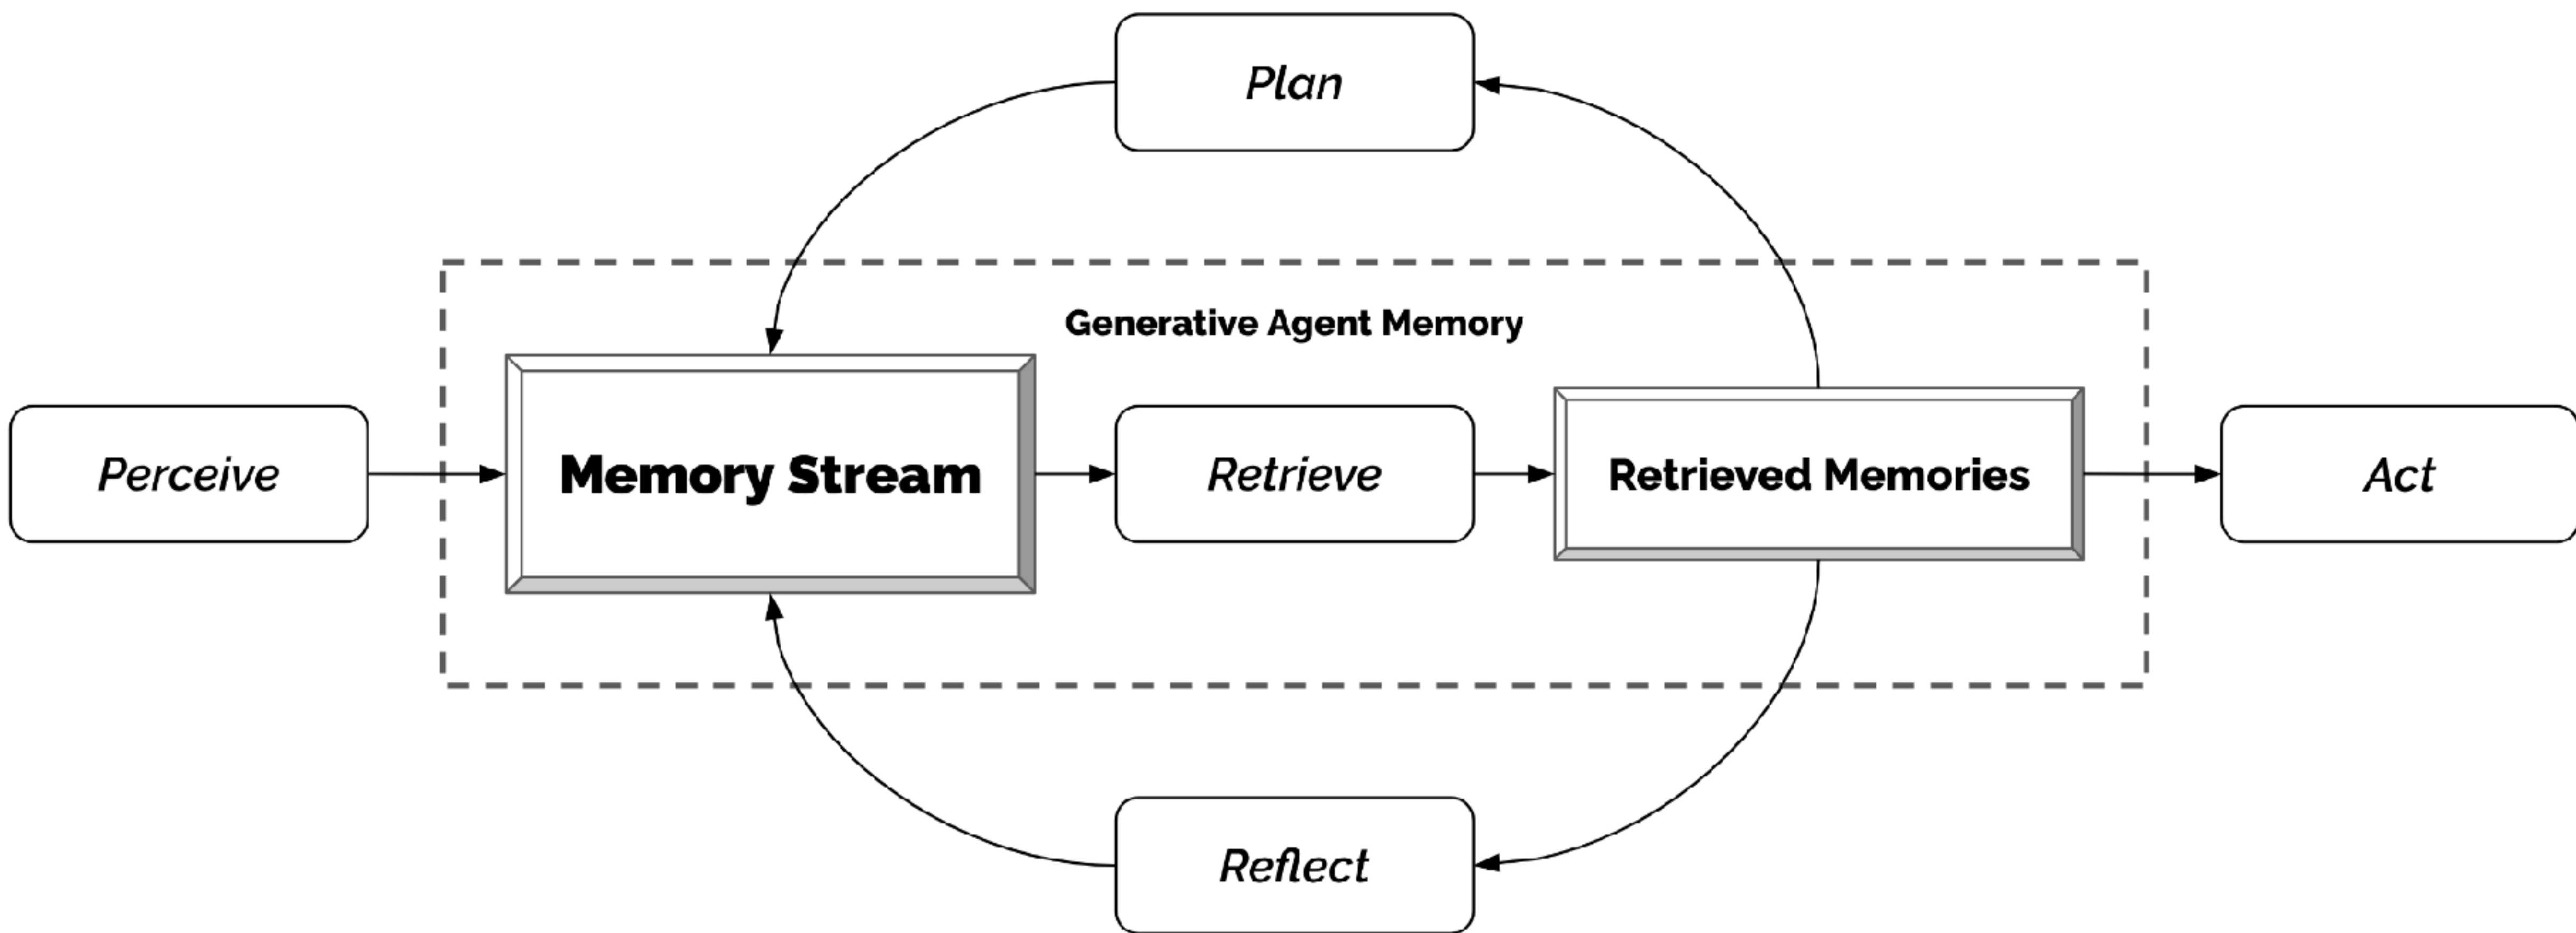

Goes for a run

Cooks breakfast

Heads to class

Isabella is initialized with an intent to plan a Valentine's Day Party

She tells customers at her cafe

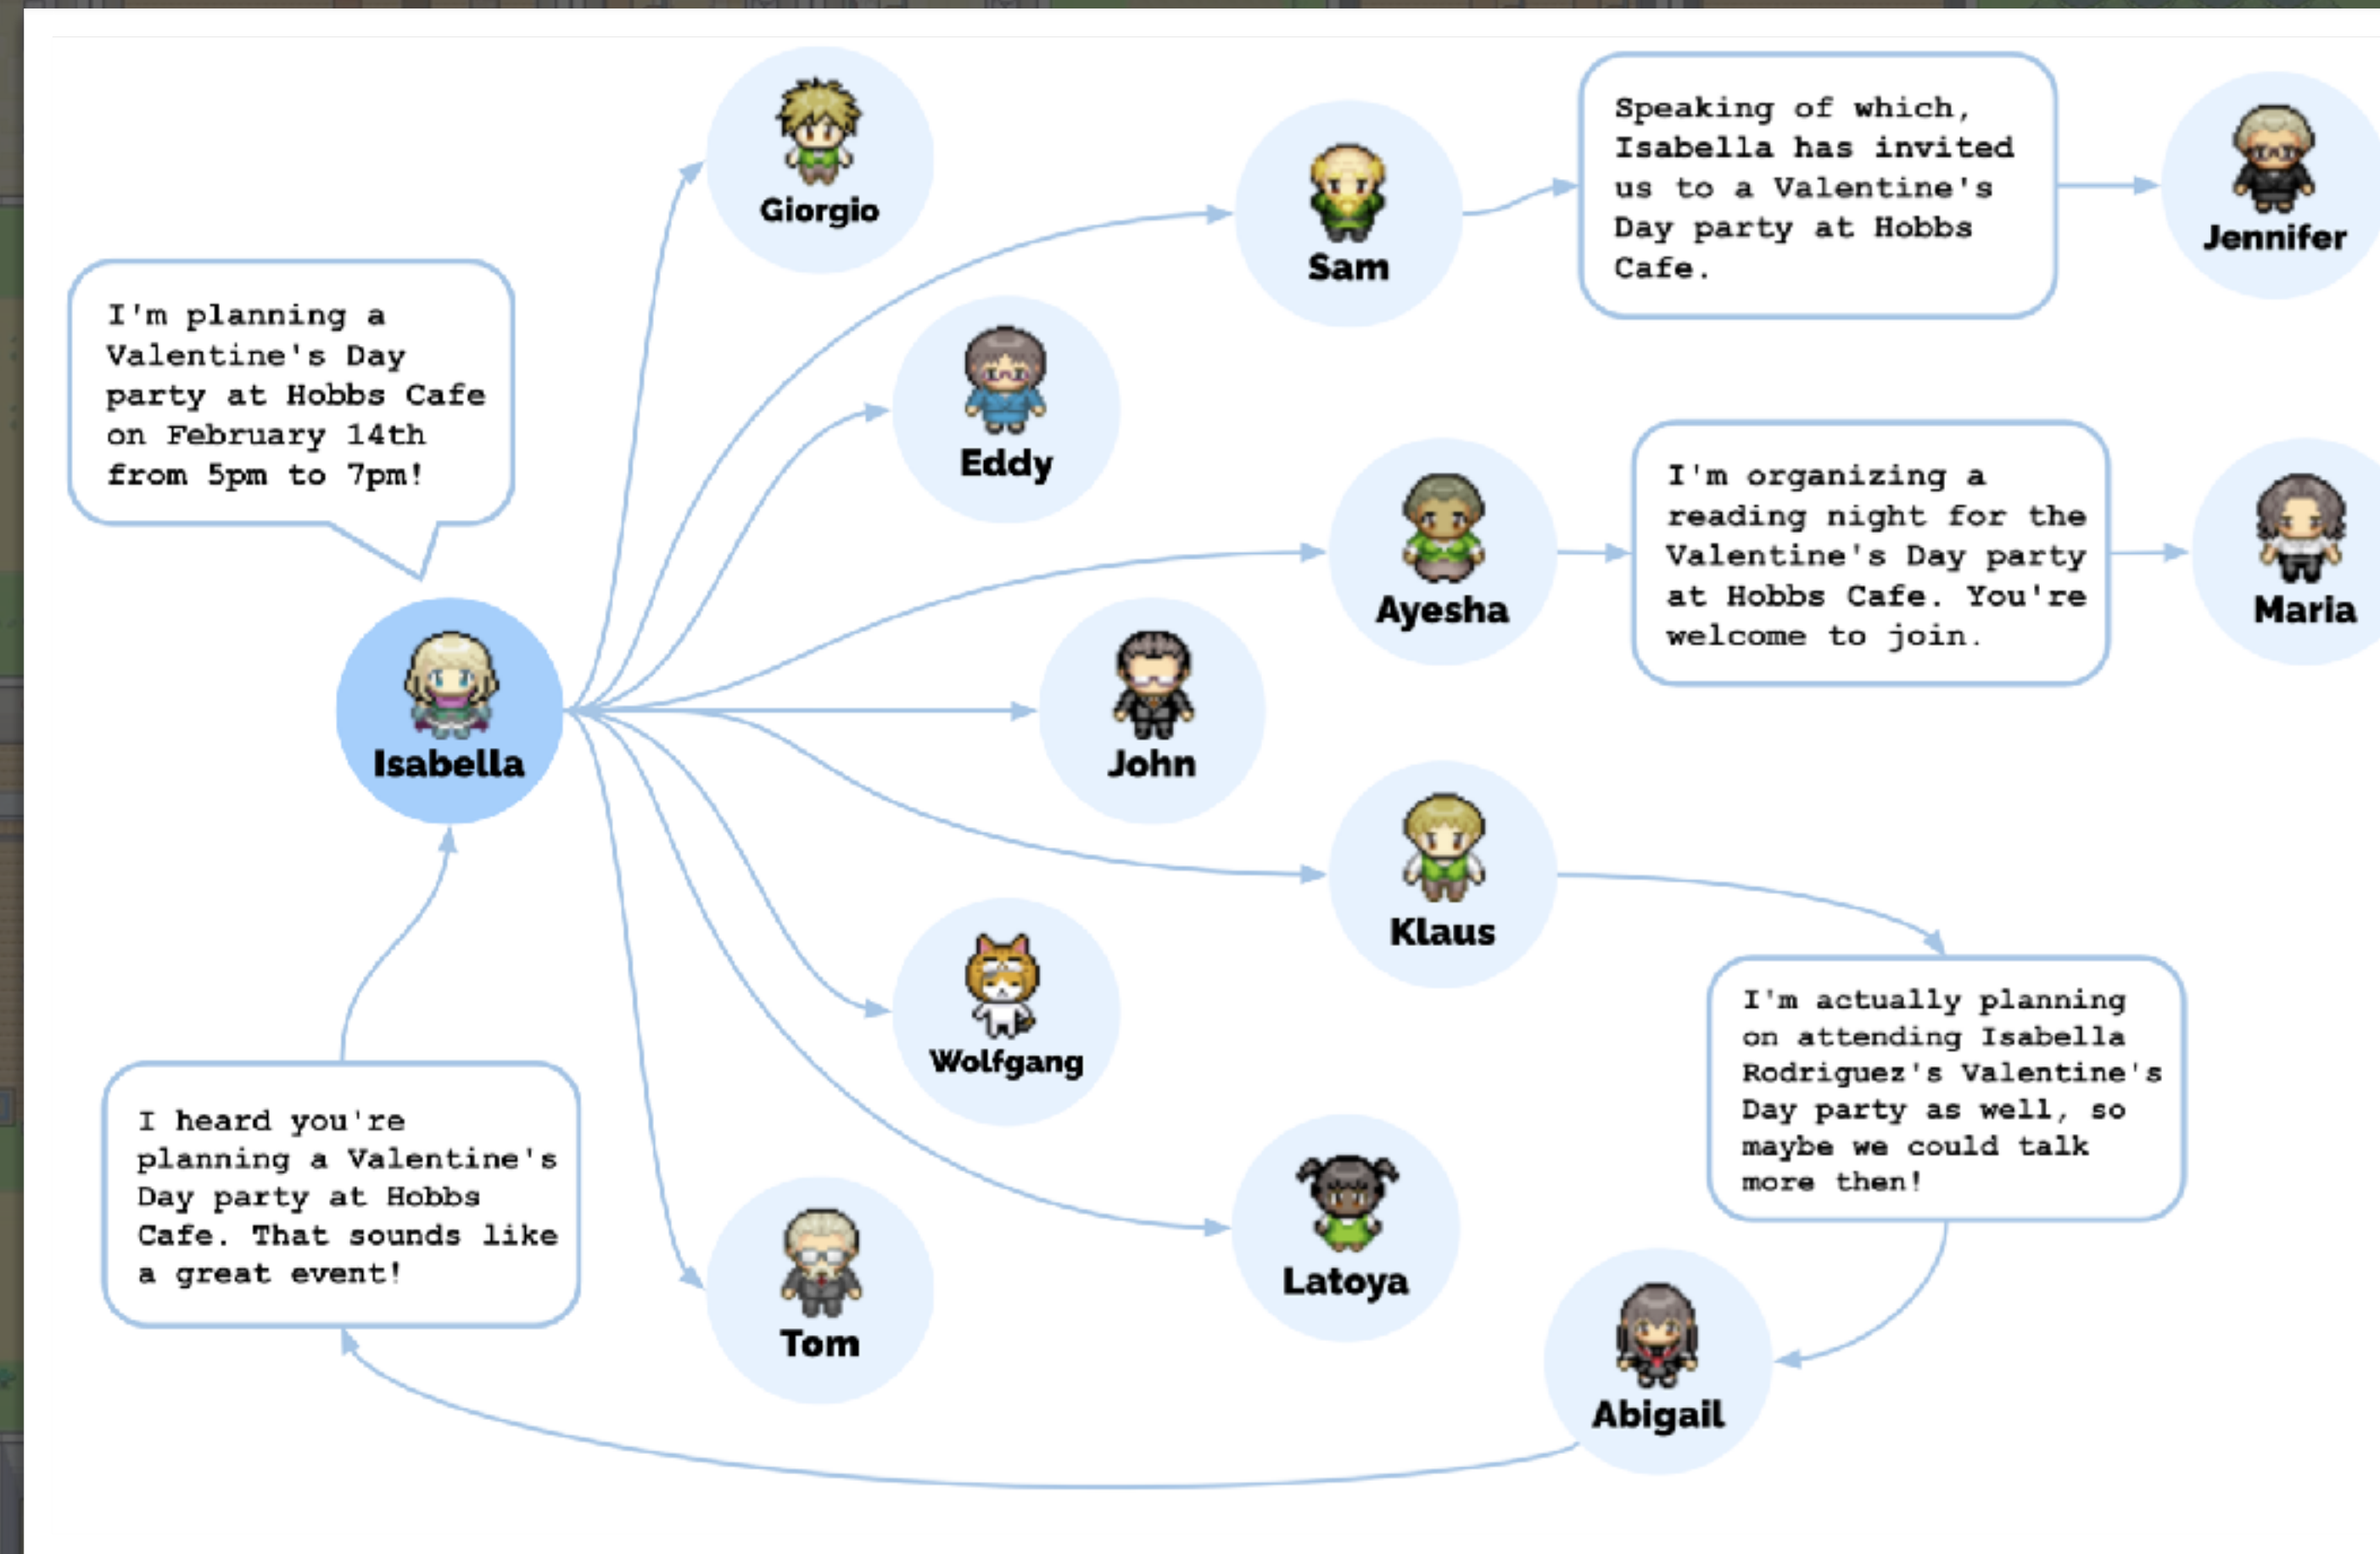

Twelve hear about it

Five came

Three cited conflicts: e.g., Rajiv, a painter: "I'm focusing on my upcoming show, and I don't really have time."

Four showed interest but didn't come

Maria asks her crush, Klaus, to the party

Simulation: iterate and test ideas

Implement

Understanding: engagement and theory yield ideas

Simulation: iterate and test ideas

Piloting: behavioral grounding

RCTs: test

Implement

Stepping back, what other models of cognition might inform HCI?

Thinking in the world

Cognition for ubiquitous computing environments

Recall: “Pictures Under Glass”
[Victor 2011]

Embodied cognition

[Dourish 2004; Klemmer, Hartmann, Takayama 2006]

Our cognition leverages **embodiment**—our bodies:

- We learn through interaction with the world

- We leverage the environments around us to make us smarter

- We communicate our intent through much broader mechanisms than just our fingertips: consider musicians, dancers, construction workers, professors on stage trying to get your attention

Epistemic action

[Kirsh and Maglio 1994]

Tetris as an example task to study cognition

Players see a piece, rotate it, and drop it into position

However, experts perform more rotations than strictly needed to position the piece. Why?

We perform actions in the world to uncover information that is hard for us to compute mentally

Hatched area:
required to
position
the piece

Gray area:
extraneous
rotations

Distributed cognition

[Hutchins 1995]

Theory: social and physical environments, not just people, can exhibit intelligence

Source: ethnography on the navigation bridge of Navy ships

Intelligent navigation is **emergent** — from people who coordinate via structured codes, and from their tools

Intelligent navigation does not reside within any single individual

Implication: when analyzing a system, **look for cognition that arises between people or between people and artifacts**

Cognitive limitations

“In an information-rich world, the wealth of information means a dearth of something else: a scarcity of whatever it is that information consumes.

What information consumes is rather obvious: it consumes the attention of its recipients.

Hence a wealth of information creates a poverty of attention and a need to allocate that attention efficiently among the overabundance of information sources that might consume it.”

- Herb Simon [1971]

Information overload

As we get more and more information in our environments, we cease being able to make effective use of it — our decision making stops improving or even gets worse

Yerkes-Dodson Law: as arousal (not volume of information) increases, performance increases, but only to a point [Yerkes and Dodson 1908]

Multitasking has costs

People have ~10 different working spheres per day, and spend 11.5 min per working sphere before switching [González and Mark 2004]

When someone gets interrupted, they take 25 minutes on average before resuming [Mark, González, and Harris 2005]

People who self-report as high multitaskers are actually worse at multitasking [Ophir et al. 2009]

Proposed mechanism: worse at filtering out irrelevant stimuli

Summary

Cognitive models create **computational proxies of human behavior**, to help us characterize and understand how we will engage with a piece of technology

- Model human processor: GOMS, KLM

- These models are powerful but can err when they make predictions out of domain

Generative AI models can also offer us broad simulation capabilities, at the risk of introducing other forms of error due to their black-box nature
